One of the most common and time consuming forms of cancer treatment is the utilization of radiation to destroy cancerous tumors, particularly in breast or prostate cancer. While radiation therapy has proven effective, the delivery of the radiation to the

tumor is done with a great deal of skill by specially trained physicians or radiation oncologists. To insure that the proper amount of radiation is delivered to the tumor, a two dimensional x-ray image is utilized to guide the radiation delivery. The radiation oncologist or physician will utilize an x-ray

simulator during a radiation treatment session in order to determine the proper location of the radiation beams for radiating the tumor. Typically, the x-ray simulator is used to simulate radiation treatment on one breast of a patient. Radiation treatment typically takes place for 6-8 weeks due to the amount of

radiation the patient receives, and the effects of the radiation for curing the cancer. In order for the patient to keep the radiation to a minimum, the x-ray simulator is operated periodically during treatment, thereby treating one breast at a time. Conventionally, the radiation oncologist has used the x-ray simulator to make a

comparative study of the two breasts of the patient, as the relative size of the tumor in each breast is not exactly the same. Additionally, since radiation therapy is designed to destroy the tumor and not the surrounding healthy cells, a radiation oncologist is able to make an educated guess on the placement

of the radiation beams based on the relative size of the tumor and the amount of healthy tissue surrounding the tumor. Many improvements to the conventional x-ray simulator have been developed, including, among others, the x-ray simulator used by the applicant of this application. These prior known x-

ray simulators are designed to allow a radiation oncologist to simulate radiation treatment to the right and left breasts of a patient in a continuous or substantially continuous manner. Nevertheless, these prior known x-ray simulators are rigid, requiring a patient to hold the simulator in a fixed position at all

times during simulation. As a result, significant time is lost during a radiation simulation due to the time spent by the patient in holding a simulator in a fixed position at one time, and the time spent changing the position of the patient's arms to position the other breast of the patient above a radiation source at the other

time. Accordingly, there is a need in the art for an improved x-ray simulator which alleviates the problems present with prior known x-ray simulators.Monoclon

Abnormal lumen morphology in

in vitro aged iliac vessels: implications for the development of iliac artery aneurysms. An experimental model has been used to examine the morphological changes which occur in the inner surfaces of iliac arteries of rats after 3 months of normal ageing. Arteries from young adult rats

were used as controls. In rat iliac artery, the wall is covered by a layer of smooth muscle cells (SMCs) and the lumen is bounded by the media and by a discontinuous endothelium. Substantial reorganization of the inner layers of iliac artery occurs after 3 months of normal ageing. The media thins, the lumen at a

part of its length becomes narrow, a number of smooth muscle cells rupture and degenerate, and the inner surface of the artery becomes irregularly textured. Such changes could lead to the development of iliac artery aneurysms.Campus Communications Campus Communications is a company

Now it shows as "VLC movie player" at the top of the screen. ~~~ Piskvorrr Thanks for the release! As a happy user of VLC, I'm somewhat envious; OS X handles these situations in a peculiarly awkward and half-ass-ish manner.
