Many of the effects you can create for your photographs can be achieved by using built-in tools provided by Photoshop. Photoshop features a host of wonderful features that enable you to remove graffiti, remove ugly blemishes from your photos, and correct the color of your images, among many other things. The Editor in Your Toolbox If you find yourself struggling with the editing interface in Photoshop, be sure to check out the link to the help documentation at "www.adobe.com/support/photoshop.html". The most common tool that most people use for editing is the pencil tool. The pencil tool is great for editing small, simple objects like text and basic shapes. There is no reason you can't use the pencil tool in Photoshop even if you are an advanced user. In the most common use of the pencil tool, you select the area you want to edit and then change its color. You can work with a number of different tools, including the eraser, color wheel, or paintbrush. Editing with the Pencil Tool To start using the pencil tool, select it from the Tools panel of the workspace. To select an area with the pencil tool, simply click anywhere in the area and draw a line. You can also click and hold to create a marquee, which then lets you move the selection to a new location. While you can use the pencil tool to create a selection, it's more often used to modify and edit the selection. Figure 2-14 shows a pencil selection. When you use the pencil tool in this way, you don't need to keep the marquee tool active. Figure 2-15 shows the same pencil selection with a layer mask. Notice that the background is visible in the mask. You'll use that to mask out unwanted areas in future steps.

Molecular cloning of bovine prolactin cDNA and determination of its expression in tissue-specific manner during lactation. We have cloned and sequenced cDNA for bovine prolactin (PRL). This cDNA is 2164 nucleotides in length and was obtained by screening a lambda gt11 expression cDNA library prepared from the bovine pituitary gland. The structural features of bovine PRL, as deduced from its cDNA, was similar to those of the other mammalian PRLs. An open reading frame encodes a protein of 67 amino acids, which exhibits higher homology to human and goat PRL than to ovine or equine prolactin. We have demonstrated that the level of mRNAs for bovine PRL in the pituitary gland is 3- to 4-fold higher at 3 days postpartum than at 5 days postpartum, while the levels of mRNAs for PRL are lower in the mammary gland than in the pituitary gland. These results indicate that bovine PRL is synthesized in a tissue-specific manner. Northern blot analysis of poly(A)+ RNA isolated from the mammary gland of midpregnant cows, pituitary gland of lactating cows, and mammary gland of midpregnant heifers and postpartum cows revealed that the levels of bovine PRL-mRNA varied in accordance with the changes in PRL concentrations. The present study has shown that the transcription of bovine PRL gene occurs in a tissue-specific manner during lactation.
